

Chusky Agent Computer

A computer for the work between words

Chusky gives an agent a private Daytona workspace where it can install dependencies, shape interfaces, run commands, inspect a desktop, and return a working artifact. The result is not only an answer. It is a place where the answer can become real.

- Private owner-scoped workspace with durable files and projects
- Bounded terminal, PTY, code, Git, and language-server workflows
- Native desktop control for local applications and visual inspection
- Signed previews for apps that are ready for a human to open

The loop from intent to artifact

A good agent loop is visible from the first brief to the final handoff. Chusky keeps the work inspectable: it verifies what it runs, preserves the useful state, and gives the owner a direct way to open the result.

Stage	What Chusky does	Evidence
Understand	Turns a brief into bounded work	Scoped objective and plan
Build	Uses the Daytona computer and runtime	Files, commands, and logs
Inspect	Checks structure and visual output	QA result and screenshot
Hand back	Registers the finished deliverable	Artifact receipt or preview URL

Capabilities that compound

The computer is useful because its capabilities work together. A generated report can be inspected, a project can be started behind a signed URL, and a follow-up can resume from the same durable workspace instead of beginning again.

Capability	Designed for	Boundary
Workspace	Code, files, packages, and projects	Private to the owner
Computer Use	Desktop applications and local GUI work	Not ordinary web browsing
App Preview	A human testing a running application	Signed and time-limited
Artifacts	PDF, DOCX, PPTX, and XLSX delivery	Generated and QA checked

A calmer handoff

The best handoff is specific enough to trust. It names what was made, shows where it can be opened, and keeps uncertainty visible. That is why Chusky treats verification and delivery as part of the work rather than a final afterthought.

- A preview link is returned only after the app server answers
- Documents pass structural checks before they are registered
- Visual QA evidence stays attached to the artifact workflow
- Destructive, external, and permission-changing actions remain gated
